## Introduction

The MMITBURN contract allows the owner to burn tokens periodically or on demand. The contract uses the SafeMath library for arithmetic operations and the IERC20 interface to interact with the token contract.

The `burnTimechange` function allows the owner to change the `burnInterval` variable.

The `startBurn` function allows the owner to burn 1% of the token balance if the last burn was at least `burnInterval` seconds ago. It checks if there are enough tokens to burn and transfers the tokens to the zero address (which is a way to burn tokens).

The `Burn` function allows the owner to burn a specific amount of tokens. It checks if there are enough tokens to burn and transfers the tokens to the zero address.

The `TokensBurned` event is emitted whenever tokens are burned.

# Diagnostics

● Critical ● Medium ● Minor / Informative

●	L20	Succeeded Transfer Check	Unresolved

## TUU - Time Units Usage

Criticality	Minor / Informative
Location	MMITBURN.sol#L301
Status	Unresolved

### Description

The contract is using arbitrary numbers to form time-related values for the variable `burnInterval`. As a result, it decreases the readability of the codebase and prevents the compiler to optimize the source code.

```
uint256 public burnInterval = 7776000 seconds;// 90 days interval;
```

### Recommendation

It is a good practice to use the time units reserved keywords like `seconds`, `minutes`, `hours`, `days`, `weeks`, and `years` to process time-related calculations.

It's important to note that these time units are simply a shorthand notation for representing time in seconds, and do not have any effect on the actual passage of time or the execution of the contract. The time units are simply a convenience for expressing time in a more human-readable form.

## RZAB - Redundant Zero Amount Burn

Criticality	Minor / Informative
Location	MMITBURN.sol#L315
Status	Unresolved

### Description

There are code segments that could be optimized. A segment may be optimized so that it becomes a smaller size, consumes less memory, executes more rapidly, or performs fewer operations.

The contract `Burn` function performs the burning functionality even if zero amount is provided.

```
function Burn(uint256 amount) external onlyOwner {
    uint256 balance = token.balanceOf(address(this));
    require(amount <= balance, "Not Enough balance");
    token.transfer(0x0000000000000000000000000000000000000000000000000000000000000000, amount);
    // Burn tokens by transferring to the zero address
    lastBurnTime = block.timestamp;
    emit TokensBurned(amount);
}
```

### Recommendation

The team is advised to take these segments into consideration and rewrite them so the runtime will be more performant. That way it will improve the efficiency and performance of the source code and reduce the cost of executing it.

The contract could integrate a sanity check on the burn amount. The burn amount should be greater than zero.

## CR - Code Repetition

Criticality	Minor / Informative
Location	MMITBURN.sol#L315,324
Status	Unresolved

### Description

The contract contains repetitive code segments. There are potential issues that can arise when using code segments in Solidity. Some of them can lead to issues like gas efficiency, complexity, readability, security, and maintainability of the source code. It is generally a good idea to try to minimize code repetition where possible.

```
require(burnAmount > 0, "No tokens available to burn.");
token.transfer(0x00000000000000000000000000000000dEaD, burnAmount);
// Burn tokens by transferring to the zero address
lastBurnTime = block.timestamp;
emit TokensBurned(burnAmount);
```

### Recommendation

The team is advised to avoid repeating the same code in multiple places, which can make the contract easier to read and maintain. The authors could try to reuse code wherever possible, as this can help reduce the complexity and size of the contract. For instance, the contract could reuse the common code segments in an internal function in order to avoid repeating the same code in multiple places.

## RSML - Redundant SafeMath Library

Criticality	Minor / Informative
Location	MMITBURN.sol
Status	Unresolved

### Description

SafeMath is a popular Solidity library that provides a set of functions for performing common arithmetic operations in a way that is resistant to integer overflows and underflows.

Starting with Solidity versions that are greater than or equal to 0.8.0, the arithmetic operations revert on underflow and overflow. As a result, the native functionality of the Solidity operations replaces the SafeMath library. Hence, the usage of the SafeMath library adds complexity, overhead and increases the gas consumption unnecessarily.

```
library SafeMath {...}
```

### Recommendation

The team is advised to remove the SafeMath library. Since the version of the contract is greater than `0.8.0` then the pure Solidity arithmetic operations produce the same result.

If the previous functionality is required, then the contract could exploit the `unchecked { ... }` statement.

Read more about the breaking change on

<https://docs.soliditylang.org/en/v0.8.16/080-breaking-changes.html#solidity-v0-8-0-breaking-changes>.

## IDI - Immutable Declaration Improvement

<b>Criticality</b>	Minor / Informative
<b>Location</b>	MMITBURN.sol#L304,305
<b>Status</b>	Unresolved

### Description

The contract is using variables that initialize them only in the constructor. The other functions are not mutating the variables. These variables are not defined as `immutable`.

```
token  
owner
```

### Recommendation

By declaring a variable as immutable, the Solidity compiler is able to make certain optimizations. This can reduce the amount of storage and computation required by the contract, and make it more gas-efficient.

## L04 - Conformance to Solidity Naming Conventions

Criticality	Minor / Informative
Location	MMITBURN.sol#L320
Status	Unresolved

### Description

The Solidity style guide is a set of guidelines for writing clean and consistent Solidity code. Adhering to a style guide can help improve the readability and maintainability of the Solidity code, making it easier for others to understand and work with.

The followings are a few key points from the Solidity style guide:

1. Use camelCase for function and variable names, with the first letter in lowercase (e.g., myVariable, updateCounter).
2. Use PascalCase for contract, struct, and enum names, with the first letter in uppercase (e.g., MyContract, UserStruct, ErrorEnum).
3. Use uppercase for constant variables and enums (e.g., MAX\_VALUE, ERROR\_CODE).
4. Use indentation to improve readability and structure.
5. Use spaces between operators and after commas.
6. Use comments to explain the purpose and behavior of the code.
7. Keep lines short (around 120 characters) to improve readability.

```
function Burn(uint256 amount) external onlyOwner {
    uint256 balance = token.balanceOf(address(this));
    require(amount <= balance, "Not Enough balance");

    token.transfer(0x00000000000000000000000000000000dEaD,
amount); // Burn tokens by transferring to the zero address
    lastBurnTime = block.timestamp;
    emit TokensBurned(amount);
}
```

### Recommendation

By following the Solidity naming convention guidelines, the codebase increased the readability, maintainability, and makes it easier to work with.

Find more information on the Solidity documentation

<https://docs.soliditylang.org/en/v0.8.17/style-guide.html#naming-convention>.

## L19 - Stable Compiler Version

Criticality	Minor / Informative
Location	MMITBURN.sol#L2
Status	Unresolved

### Description

The `^` symbol indicates that any version of Solidity that is compatible with the specified version (i.e., any version that is a higher minor or patch version) can be used to compile the contract. The version lock is a mechanism that allows the author to specify a minimum version of the Solidity compiler that must be used to compile the contract code. This is useful because it ensures that the contract will be compiled using a version of the compiler that is known to be compatible with the code.

```
pragma solidity ^0.8.0;
```

### Recommendation

The team is advised to lock the pragma to ensure the stability of the codebase. The locked pragma version ensures that the contract will not be deployed with an unexpected version. An unexpected version may produce vulnerabilities and undiscovered bugs. The compiler should be configured to the lowest version that provides all the required functionality for the codebase. As a result, the project will be compiled in a well-tested LTS (Long Term Support) environment.

## L20 - Succeeded Transfer Check

<b>Criticality</b>	Minor / Informative
<b>Location</b>	MMITBURN.sol#L316,323
<b>Status</b>	Unresolved

### Description

According to the ERC20 specification, the transfer methods should be checked if the result is successful. Otherwise, the contract may wrongly assume that the transfer has been established.

```
token.transfer(0x00000000000000000000000000000000dEaD,  
burnAmount)  
token.transfer(0x00000000000000000000000000000000dEaD,  
amount)
```

### Recommendation

The contract should check if the result of the transfer methods is successful. The team is advised to check the SafeERC20 library from the [Openzeppelin library](#).

This report may not be transmitted, disclosed, referred to or relied upon by any person for any purposes nor may copies be delivered to any other person other than the Company without Cyberscope's prior written consent. This report is not nor should be considered an "endorsement" or "disapproval" of any particular project or team. This report is not nor should be regarded as an indication of the economics or value of any "product" or "asset" created by any team or project that contracts Cyberscope to perform a security assessment. This document does not provide any warranty or guarantee regarding the absolute bug-free nature of the technology analyzed, nor do they provide any indication of the technologies proprietors' business, business model or legal compliance. This report should not be used in any way to make decisions around investment or involvement with any particular project. This report represents an extensive assessment process intending to help our customers increase the quality of their code while reducing the high level of risk presented by cryptographic tokens and blockchain technology.

Blockchain technology and cryptographic assets present a high level of ongoing risk. Cyberscope's position is that each company and individual are responsible for their own due diligence and continuous security. Cyberscope's goal is to help reduce the attack vectors and the high level of variance associated with utilizing new and consistently changing technologies and in no way claims any guarantee of security or functionality of the technology we agree to analyze. The assessment services provided by Cyberscope are subject to dependencies and are under continuing development. You agree that your access and/or use including but not limited to any services reports and materials will be at your sole risk on an as-is where-is and as-available basis. Cryptographic tokens are emergent technologies and carry with them high levels of technical risk and uncertainty. The assessment reports could include false positives, false negatives and other unpredictable results. The services may access and depend upon multiple layers of third parties.

## About Cyberscope

Cyberscope is a blockchain cybersecurity company that was founded with the vision to make web3.0 a safer place for investors and developers. Since its launch, it has worked with thousands of projects and is estimated to have secured tens of millions of investors' funds.

Cyberscope is one of the leading smart contract audit firms in the crypto space and has built a high-profile network of clients and partners.
